Let's Start!

What can we use ASP.NET for?

Learning Outcome:

Describe common simple incidents at work in a simple spoken or written situation with a supportive interlocutor.

Represent the solution outline to the problem presented by the customer through making case of use diagrams, facing the problem to the customer following rules and protocols of the organization.

Ask your partner:

- What web development platforms do you know?
- What computer languages can be used in a web development platform?

Can Do Statements:

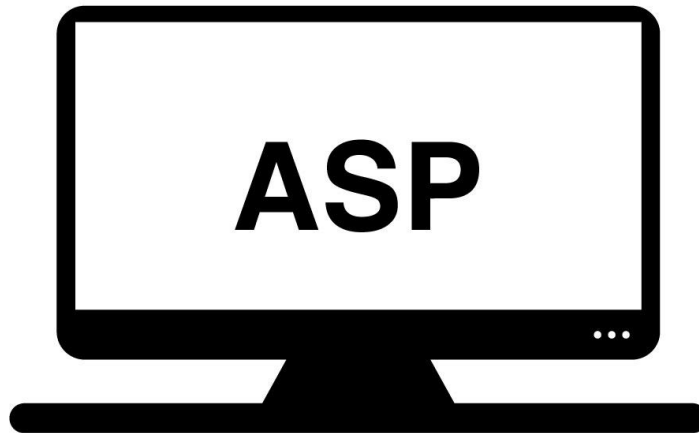

- I can understand written information about the ASP.NET web development platform.
- I can identify basic information about stateless protocols.
- I can locate the main ideas in a passage about technology.

Let's Explore!

A web development student writes a report about ASP.NET.

Instructions: Read the text below.

ASP.NET is a free web framework that allows developing dynamic websites, data-driven applications or web services for different computer devices. This software framework makes part of Microsoft's .Net, a platform where programmers can have access to different tools and data bases to create HTML sites.

One of .NET framework most remarkable features is that it uses Common Language Runtime which makes possible to write application codes in different types of computer languages such as Visual Basic, C# and Jscript.

Besides that, ASP.NET offers two kinds of web forms: on the one hand, a web application format and, on the other hand, a website format. The first format requires compilation before runtime while in the second one users can copy files straight to a server.

When using ASP.NET, web developers can put applications online in any kind of browser by means of HTTP protocols and HTTP commands that transfer information from servers to browsers. To clear the concept, HTTP is a stateless protocol that can process each code request separately, so that web applications can be available between server and users.

ASP.NET pages store information in two ways of interaction during a user session: page state and session state. In page state, there is all the information concerning the user actions on a website, for example, the items a user puts in an online shopping car. While in the session state, you can find all the data referring to the user's navigation throughout different webpages, for instance, all the products the user checks before deciding to buy one. Then, web browsers can use cookies to keep track of the data provided in page state and session state.

Let's Practice!

Laura takes notes about stateless protocols.

Instructions: Classify the sentences by writing the number of the sentence in the correct category.

1. I can process code requests separately.
2. I can get access to different data bases to create HTLM sites.
3. I can develop dynamic websites.
4. I can transfer information from servers to browsers.

What can you do with stateless protocols?	What can you do with ASP.NET?

Let's Practice!

Laura reads an article about ASP.NET web development platform.

Instructions: Cross out the incorrect word and write in the correct word.

1. Microsoft's .Net is a platform where programmers_____ HTLM sites. (can create / can to create)
2. Web developers _____ applications online. (can puts / can put)
3. HTTP _____ each code request separately. (can processes / can process)
4. Web applications _____ (can being / can be) available between server and users.
5. ASP.NET pages _____ (can to store / can store) information in two ways of interaction.

Extension Activity

Let's write a short text bout technology!

Instructions: Complete the following steps. Fill in the Self-Assessment.

- Choose a topic related to technology.
- Look for information about the topic you chose.
- Design a brochure with general information about the technology topic.
- Explain your brochure to you instructor.

Self-Assessment

Yes

No

- I choose a topic related to technology.
- I look for information about the topic that I chose.
- I design a brochure.
- I explain my brochure to my instructor.

☐	☐
☐	☐

Target Words

- **web framework** (noun): a software that provides different tools to develop web applications.
e.g. ASP.NET is a free web framework that allows developing dynamic websites, data-driven applications or web services for different computer devices.
- **data driven application**(noun): an application where data can control the flow of a program.
e.g. ASP.NET is a free web framework that allows developing dynamic websites, data-driven applications or web services for different computer devices.
- **server** (noun): a computer program that can process and complete code requests.
e.g. the first format requires compilation before runtime while in the second one users can copy files straight to a server.
- **stateless protocol** (noun): an application that can execute code requests in an independent way, such as IP or HTTP.
e.g. HTTP is a stateless protocol that can process each code request separately, so that web applications can be available between server and users.
- **store** (verb): to save information.
e.g. ASP.NET pages store information in two ways of interaction during a user session: Page state and session state.
- **keep track of** (expression): to control information about something.
e.g. Then, web browsers can use cookies to keep track of the data provided in page state and session state.

Learning Points

Modal Verb Can to Talk About Possibilities

We use the modal **can** in English to express the possibility of something happening.

You can make use of the modal **can** to talk about the possibilities that ASP.NET features offer:

- You **can** write ASP.NET application codes in several languages.
- Application codes **can** use the entire hierarchy of classes.

Look at the chart to identify the structures:

	Subject	Modal verb	Main verb	Complement
Affirmative	<i>You</i>	<i>can</i>	<i>write</i>	<i>ASP.NET application codes in several languages.</i>
Negative	<i>You</i>	<i>can't</i>	<i>write</i>	<i>ASP.NET application codes in several languages.</i>
	Modal verb	Subject	Main verb	Complement
Interrogative	<i>Can</i>	<i>you</i>	<i>write</i>	<i>ASP.NET application codes in several languages?</i>

Examples

- *This software framework makes part of Microsoft's .Net, a platform where programmers can have access to different tools and data bases to create HTML sites.*
- *When using ASP.NET, web developers can put applications online in any kind of browser by using HTTP protocol and HTTP commands that transfer information from servers to browsers.*
- *While in the session state, you can find all the data referring to the user's navigation throughout different webpages, for instance all the products the user checks before deciding to buy one.*

Learning Points

Understanding Stateless Protocols

A stateless protocol is a mechanism that allows making code requests and code responses independently.

When using stateless protocols, servers do not need to keep track of all session information users have during a communication, each pair request-response acts separately.

The most common examples of stateless protocols are:

- Internet Protocol - IP
- Hypertext Transfer Protocol - HTTP

In some cases, stateless protocols cannot prevent some dangers on the internet such as spam or hacking. To prevent these types of situations, stateless protocols work together with stateful protocols to retain more information during communications.
